

ME 597: Distributed Energy Resources

Professor: Kevin J. Kircher, kevinjkircher.com; offered in person and online

Distributed energy resources (DERs) are controllable electrical devices that plug in at the edge of the power grid, typically through buildings. DERs – such as electric vehicles, heating and cooling equipment, energy storage systems, and rooftop solar photovoltaics – will play an increasingly important role in future energy systems that decarbonize, digitalize, and decentralize their operations. In this class, students will learn to model a variety of DERs, optimize DER designs, and control DERs to reduce costs, pollution, and impacts on the power grid. This class will involve a mix of coding and mathematical analysis. Students will do semester projects on current DER topics.

Topics:

- Introduction to energy, electricity, and DERs
- Modeling and simulating DER dynamics
- Fitting DER models to data
- Creating and evaluating DER designs
- Controlling DERs for cost savings, pollution reductions, and power grid services

Prerequisites:

- Facility with programming in Matlab or Python
- Familiarity with ordinary differential equations and linear algebra
